The relationship between Knowledge Management Enablers , Processes resources and organizational Performance in selected Universities of the Isfahan Province

Sima Fattahiyan[1] **,** Reza Hoveida[2] **,** Seyed ali Siadat[3], Hooshang Talebi [4]

Abstract

The purpose of this paper was to evaluate the impact of specific knowledge management resources (i.e. knowledge management enablers and processes) on organizational performance.

This study is an applied, descriptive correlationnal research. For data collection procedure, two kinds of questionnaires has been used. The first is Lee & Choi's (2003) questionnaire about knowledge management enablers types and the second one is Park's (2006) questionnaire about knowledge management dimensions. Using Cronbach's alpha coefficient , first questionnaire has 0/91 of constancy and the second has 0/90 This shows that measuring tools have high levels of constancy. Isfahan universities faculty members formed the population of this study which were randomly selected. The results showed that some knowledge resources (e.g. organizational structure, knowledge application) are directly related to organizational performance, while others (e.g. technology, knowledge conversion), though important preconditions for knowledge management, are not directly related to organizational performance.

Keywords: Knowledge   management,   Knowledge management   enablers,   knowledge management processes, Organizational performance, university.

1. Introduction

For many organizations achieving improved performance is not only dependent on the successful deployment of tangible assets and natural resources but also on the effective management of knowledge (Lee and Sukoco, 2007). Much of the overall spending by organization on knowledge management initiatives is driven by strategic imperatives that depend on the effective management of the knowledge resource (Lee and Sukoco, 2007). As such, one of the main reasons universities invest in knowledge management is to build a knowledge capability that facilitates the effective management and flow of information and knowledge within the university.

Different resources make up the knowledge capability of a university. These include technology infrastructure, organizational structure and organizational culture which are linked to a university's knowledge infrastructure capability; and knowledge acquisition, knowledge conversion, knowledge application and knowledge protection which are linked to the university's knowledge process capability (Gold et al., 2001). Taken together, these resources determine the knowledge management capability of a university, which in turn

[3] -Associate Prof. University of Isfahan
[4] -Assistant Prof. University of Isfahan

has been linked to various measures of organizational performance (Gold et al., 2001; Lee and Sukoco, 2007; Zack et al., 2009).

2. Literature review

Gold et al. (2001) proposed a model of knowledge management capabilities that has since become one of the most widely cited in the knowledge management literature. In this model, Gold et al. theorized knowledge management capabilities as multidimensional concepts that incorporate: a process perspective which focuses on a set of activities, that is, knowledge process capabilities and an infrastructure perspective which focuses on enablers, that is, knowledge infrastructure capabilities (Lee and Choi, 2003). These in turn are composed of multiple dimensions: knowledge infrastructural capability comprises technology, organizational culture and organizational structure while knowledge process capability is made up of knowledge acquisition, knowledge conversion, knowledge application, and knowledge protection (Gold et al., 2001).

However, what is not well known is whether there are differential relationships (including null or cancelling effects) between the individual dimensions of knowledge process capability and knowledge infrastructure capability, and organizational performance and the nature of these relationships (Petter et al., 2006). To address this gap, this study examines a decomposed Gold et al. (2001) model, analyzing the structural model at the level of the individual resource in contrast organizational performance. The outcomes are expected to provide specific insights into the knowledge management – organizational performance link by identifying those knowledge resources (i.e. enablers and processes) that are directly related to organizational performance.

Based on this understanding of the relationship between resources, capabilities- infrastructure and process- and organizational performance, the next section examines knowledge management capabilities, the resources that make up these capabilities, and the theorized links between these resources and organizational performance. A decomposed model of knowledge management capabilities is then assessed in contrast organizational performance, and the results compared with a composite model of knowledge management capabilities.

2.1 Knowledge infrastructure capability. Prior research recognizes the importance of having a supportive and effective knowledge infrastructure to underpin a university's knowledge management initiatives (Davenport and Völpel, 2001). Different elements make up a university's knowledge infrastructure capability. This study adopts the Gold et al. (2001) typology which views technology, organizational culture and organizational structure as key components of a university's knowledge infrastructure capability.

2.1.1 Technology

The technology element of knowledge infrastructure comprises the information technology (IT) systems that enable the integration of information and knowledge in the organization as well as the creation, transfer, storage and safe-keeping of the university's knowledge resource(Webb and Schlemmer,2006).

2.1.2 Organizational culture

In the context of knowledge management is considered a complex collection of values, beliefs, behaviors and symbols that influences knowledge management in organizations (Ho,2009). Sin and Tse (2000) found that organizational cultural values such as consumer

orientation, service quality, informality and innovation were ''significantly associated with marketing effectiveness''. More recently, Aydin and Ceylan (2009) also showed that cultural dimensions were related to organizational performance.

2.1.3 Organizational structure

Organizational structure comprises the organizational hierarchy, rules and regulations, and reporting relationships (Herath, 2007) and is considered a means of co-ordination and control whereby organizational actors can be directed towards organizational effectiveness.

Knowledge management theorists largely conclude that changes in an organization's structure, such as moving from hierarchical to flatter networked forms, are essential for the effective transfer and creation of knowledge in the organization (Nonaka and Takeuchi, 1995).

2. 2 Knowledge process capability

Gold et al. (2001) suggested that knowledge process capabilities (required for storing, transforming and transporting of knowledge throughout the organization) are needed for leveraging the infrastructure capability. Four broad dimensions are identified – ''acquiring knowledge, converting it into useful form, applying or using it, and protecting it'' (Gold et al., 2001, p. 190).

2.2.1 Knowledge acquisition

The term ''acquisition'' refers to a university's capability to identify, acquire and accumulate knowledge (whether internal or external) that is essential to its operations (Gold et al., 2001; Zahra and George, 2002). Acquiring knowledge can involve several aspects including creation, sharing and dissemination. Knowledge acquisition reflects in part, a subset of a university's absorptive

2.2.2 Knowledge conversion

Knowledge that is captured from various sources (both internal and external to the business) needs to be converted to organizational knowledge for effective utilization within the business (Lee and Suh, 2003). This conversion process, which takes place along the supply chain of data, information and knowledge, is transient in nature and so organizations must speedily convert data into information and information into organizational knowledge to maximize benefits from the conversion process (Bhatt, 2001).Thus, it is expected that the knowledge conversion process could influence performance outcomes.

2.2.3 Knowledge application

Bhatt (2001) stated that: ''knowledge application means making knowledge more active and relevant for the organization in creating value''. For organizations to create value they need to apply knowledge to their products and services by various means such as repackaging available knowledge, training and motivating its people to think creatively, and utilizing people's understanding of the company's processes, products and services.

2.2.4 Knowledge protection

Knowledge protection is necessary for effective functioning and control within organizations. This would typically include the use of copyright and patents along with information technology systems that allow knowledge to be secured by filename, user name, password and file-sharing protocols that ascribe rights to authorized users (Lee and Yang, 2000).

3.Research Hypotheses

The aim of the present study is to investigate the relationship between knowledge management enablers and processes with organizational performance in selected universities of Isfahan province. In this research the relationship between three different kinds of knowledge management enablers, namely technology, organizational culture, organization structure and four different kinds of knowledge management processes, namely knowledge acquisition, conversion, application and protection with organizational performance in selected universities is examined.

3.1 Major Research Hypothesis

There is relationship between knowledge management enablers (Technology, Organizational culture, Organizational structure) and processes (Knowledge acquisition, conversion, application, application) with organizational performance in selected universities of Isfahan province.

3.2 Secondary Research Hypotheses

*H1.*There is relationship Technology and organizational performance in selected universities of Isfahan province.
*H2. H1.*There is relationship Organizational culture and organizational performance in selected universities of Isfahan province.
*H3.*There is relationship Organizational structure and organizational performance in selected universities of Isfahan province.
*H4.*There is relationship Knowledge acquisition and organizational performance in selected universities of Isfahan province.
*H5.*There is relationship Knowledge conversion and organizational performance in selected universities of Isfahan province.
*H6.*There is relationship Knowledge application and organizational performance in selected universities of Isfahan province.
*H7.*There is relationship Knowledge protection and organizational performance in selected universities of Isfahan province.
*H8.*There is relationship Knowledge infrastructural capability and organizational performance in selected universities of Isfahan province.
*H9.*There is relationship Knowledge process capability and organizational performance in selected universities of Isfahan province.

4. Research Methodology

This study is applied, correlationnal descriptive research and is categorized as field study. To collect related literature, related books, articles and journals were consulted as data collection procedure and analyzing the collected data, two kinds of questionnaires has been used. The first is Lee & Choi's (2003) questionnaire about knowledge management

enablers types and the second of one is Park's (2006) questionnaire about knowledge management dimensions. Each questionnaire contained 27 questions. Subjects answered the relevant questions based on a 5 degree Likert scale. Using Cronbach's alpha coefficient the first questionnaire has 0/91 of constancy and the second has 0/90 This shows that measuring tools have high levels of constancy. Isfahan universities faculty members formed the population of this study which were randomly selected. The whole population was about 1820 among which 220 were randomly selected. In this study for the purpose of analyzing the collected data, SPSS software was used. Also descriptive statistics (percentage, frequency, mean, standard deviation) was used to test research question inferential statistics were used.

5. Data analysis and results

PLS-Graph 3.0 (Build 1130) and SPSS version 17.0 were used to assess the links between knowledge management capabilities and organization effectiveness, and bootstrapping used to evaluate the significance of the model paths.

First, the measurement model was assessed. Ideally, item loadings should exceed 0.707; loadings of 0.60 are also acceptable if there are additional indicators. The results showed one item measuring knowledge acquisition returned a loading of 0.40; this item was therefore excluded. Item loadings for all other constructs ranged from 0.668 to 0.926 exceeding minimum thresholds (Table 1).

Descriptive statistics (i.e. mean and standard deviation) for each construct are shown in Table 2. Table 2 also shows that composite reliabilities ranged from 0.918 to 0.963 and average variance extracted (AVE) from 0.635 to 0.789 exceeding recommended cut-offs (Chin,1998). Construct AVEs were also greater than the variance shared between the constructs (Table 3) satisfying the criteria for discriminant validity (Chin, 1998).

5.1 Decomposed model of KM capabilities

Turning to the structural model, the results showed the decomposed model accounted for 0.754 of the variance observed for organizational performance. Of the knowledge infrastructural capabilities, only organizational structure ($\beta=0.209$; $p \leq 0.05$) was significant in contrast organizational performance; technology infrastructure ($\beta=-0.003$) was not expected to be significant. Hypotheses H1 and H3 were supported. Contrary to expectation, organizational culture was not significant ($\beta=0.055$); H2 was therefore not supported.

For knowledge process capability, three processes were significant in contrast organizational performance: knowledge acquisition ($\beta=0.146$; $p \leq 0.05$), knowledge application ($\beta=0.412$; $p \leq 0.001$), and knowledge protection ($\beta=0.148$; $p \leq 0.05$); H4, H6 and H7 were supported. Knowledge conversion capability was not significant ($\beta=0.025$); H5 was not supported.

5.2 Assessment of the composite model

Next, latent variable scores representing the dimensions of knowledge process capability and knowledge infrastructural capability were extracted and used to assess the composite model. Consistent with recommended guidelines, indicator weights for all seven dimensions were examined (Table 4); all except knowledge conversion were significant in contrast their respective constructs at $p \leq 0.05$ (Petter et al., 2007). However, this does not

mean knowledge conversion was unimportant. Further examination of the item loadings showed the construct demonstrated ''absolute'' importance when assessed independently of other indicators (Cenfetelli and Basellier, 2009). The results also showed that, knowledge application was the most important of the dimensions in terms of relative importance.

The results of the structural model tests showed that the composite (second-order) model accounted for 0.748 of the variance observed for organizational performance (Table 5).Consistent with expectations, knowledge infrastructural capability (β=0.251; p$\leq$ 0.05) and knowledge process capability (β=-0.639; p$\leq$ 0.001) were both significant in contrast organizational performance, supporting hypotheses H8 and H9. Finally, a summary of the results of the model tests for the decomposed model and the composite model are shown in Table 5.

6. Discussion and Implications

Consistent with expectations, the study results provided strong empirical support for the decomposed model, accounting for 0.754 of the variance observed for organizational performance. For the composite model (Table 5), the amount of variance explained was 0.748, and was similar to the decomposed model. The links between organizational performance and knowledge process capability and knowledge infrastructure capability returned path weights of 0.251 and 0.639 respectively. Altogether, these findings are consistent with prior research that has observed similar orders of magnitude for the path weights and variance explained in respect of knowledge management and organizational performance (Gold et al., 2001).

The results for the decomposed model (Table 5) showed that of the three infrastructural capabilities, only organizational structure had a significant impact on organizational performance; neither technology nor organizational culture had a significant impact on organizational performance. For knowledge process capability, knowledge acquisition, knowledge application and knowledge protection also impacted organizational performance, but not knowledge conversion.

Altogether, these results suggest that although the individual resources collectively determine the knowledge management capabilities construct, not all are directly linked to organizational performance. This is consistent with the resource-based view which suggests that only a subset of a university's capabilities when leveraged appropriately reflect direct contributions to performance measures (Grant,1996). For example, Seleim and Khalil (2007) found that of five knowledge processes studied (e.g. acquisition, creation, application) only knowledge application was directly linked to organizational performance.

So although, knowledge management capabilities may contribute directly to organizational performance and each resource significant in respect of its construct, in some cases the contribution of particular resources may be more indirect through their impact on other factors linked to organizational performance. For example, while Seleim and Khalil (2007) did not uncover a positive link between organizational performance, and knowledge acquisition and knowledge creation, their study showed both processes were directly related to knowledge application which in turn was related to organizational performance.

The study results have several implications for knowledge management in universities. For example, research suggests appropriate investments in knowledge management

initiatives can enhance organizational performance. However, this study shows that not all of the resources are direct contributors. Although resources such as technology, culture and knowledge conversion are necessary for effective knowledge management (Gold et al.,2001) they did not impact organizational performance directly. However, universities can ill afford to neglect these dimensions as they work in combination with and support other resources, such as knowledge acquisition and knowledge application that may contribute directly to organizational success (Van den Bosch et al., 1999; Seleim and Khalil, 2007).

Second, this research showed that inferences about an overall capability do not necessarily apply when it comes to individual resources. For example, the current findings are consistent with research which suggests that particular knowledge resources (e.g. technology, organizational structure, knowledge acquisition, etc) are directly related to knowledge management capabilities (Gold et al., 2001; Zack et al., 2009) and are therefore important in forming a university's overall knowledge capability. However, for studies that use composite models, it is difficult to identify which resources directly impact organizational performance. Although some studies shed light on this gap (Zack et al., 2009), there remains a gap in the literature regarding empirical evidence linking particular knowledge resources to performance. The current study addresses this gap by identifying specific enablers and processes that are directly related to organizational performance.

The combination of resources that is most effective for an organization is also likely to differ across universities. Since there are no ''silver-bullet'' combinations when it comes to enhancing organizational performance, it is incumbent on managers not only to recognize that all the resources are important, but also to identify which resources and consequently which capabilities are most salient to organizational performance. Such insights can help managers identify appropriate strategies aimed at deploying combinations of knowledge management resources that better support the university's goals. Furthermore, since the combinations may be unique across universities, this provides an opportunity for competitive advantage and sustained performance.

Although this study offers insights into the dynamic nature of the knowledge management resource, there are some constraints. For example, since a university's knowledge capability is a composite of the individual resources that make up the knowledge capability, different universities and industries may have different combinations that yield similar outcomes. As such, while the outcomes of this study suggest, for example that organizational structure was linked to organizational performance and culture was not for the study sample, the same may not apply to other settings. This can be expected as performance indicators such as competitive advantage are created and maintained by such differences. It is therefore important that universities recognize the variableness of knowledge capabilities and the need to deploy strategies that lead to the acquisition and deployment of those capabilities that are most relevant to the university's goals. As with other survey-based research, this study is subject to the possibility of response bias such that managers for reasons such as poor recall or role characteristics may under-report or over-report the knowledge management activities of their university. Having two or more respondents for each university can help minimize this effect, but may limit how many data can be collected (Gold et al., 2001).

Finally, this study also does not provide in-depth insight into the capabilities of individual universities. Such insights would enable a better understanding of the individual

capabilities that make up a university's knowledge capability, why differences may occur, and under what circumstances do some resources impact organizational performance and others do not. Future research is therefore needed to examine in greater detail the links between the individual capabilities that make up knowledge resources, and organizational performance.

7. Conclusion

The literature is replete with studies that suggest knowledge management impacts organizational performance at university. However, there has been little elaboration of the relationships at the dimensional level in contrast organizational performance. Yet when it comes to making decisions about a university's knowledge capability, these are often made at the level of the individual resource. This study addresses this gap by assessing a decomposed model of knowledge management capabilities. The aim was to provide insights into the relationships between particular knowledge resources and organizational performance that can help universities identify appropriate strategies for investing in and effectively deploying the knowledge resource.

The results showed that for the current study, organizational structure, knowledge acquisition, knowledge application and knowledge protection were significantly related to organizational performance. However, technology, organizational culture and knowledge conversion did not have a significant impact. Taken altogether, the findings suggest that although the individual resources collectively determine a university's overall knowledge management capability which, as a composite is related to organizational performance, each resource is not directly linked to performance. The decomposed model therefore offers insights into relationships at the dimensional level that are not readily inferred from composite models.

In the final analysis, this study offers useful insights into the knowledge management – performance link. First, there has been little research that decomposes the effects of knowledge management in relation to organizational performance. The results suggest the decomposed approach is useful for understanding the complex relationships embodied in the knowledge management – performance link, which cannot be surmised from a composite model. Such an approach is useful for research aimed at acquiring an in-depth understanding of knowledge management, as opposed to achieving parsimony or focusing on main effects.
